ABSTRACT

Hydatid disease or hydatid cyst results from the tissue development of the hydatid larva of an echinococcus taenia. It is an endemic disease in certain regions of the world such as the Mediterranean basin. We report here the observation of a 39 year old patient with no particular pathological history admitted for pericardial effusion revealing a cardiac hydatid. After clinical and biological explorations we made the diagnosis of a cardiac hydatid located on the inter ventricular septum. The patient was put under medical treatment because of the refusal of the surgery.

Keywords: Tamponnade; hydatid cyst; left ventricle.

1. INTRODUCTION

Hydatitosis results from the tissue development of the hydatid larva of a taenia echinococcus. Several cases have been reported in developing countries, particularly in the Mediterranean basin. Cardiac and especially pericardial involvement remains rare, in the order of 0.03 to 1.1% according to the WHO [1-2]. Its diagnosis is difficult because of the absence of specific clinical signs [3]. We report the observation of a cardiac hydatid revealed by a pericardial effusion.

2. CASE PRESENTATION

MR, 39 years old, with no particular pathological history, consulted for NYHA stage II dyspnea. Clinical examination: Patient conscious, BP=114/73 mmHg, HR=108 bpm. Cardiovascular examination: Muffled heart sounds with spontaneous turgor of the jugular vein. The rest of the examination was unremarkable.

**Biological workup:** hyperleukocytosis with eosinophilic predominance at 21% with a biological inflammatory syndrome and anemia at 10 g/dl inflammatory, hydatid serology positive.

ECG: RRS at 98 bpm fixed PR at 0.16 s, fine QRS with diffuse micro voltage.

Chest X-ray: cardiomegaly with bulging of the left inferior arch.

![Trans thoracic echocardiography](image1.png)

*Image 1. Front view of the chest showing a bulge in the left lower arch*

**Trans thoracic echocardiography:** the presence of a large pericardial effusion in pre-tamponade, with an image of cystic appearance appended to the interventricular septum, measuring 12 x 7 mm.

*Image 2: Cystic-like image of the interventricular septum*

An emergency pericardial puncture was indicated - resulted in the removal of 1 l 300 of exudative citrine yellow fluid.

Thoraco-abdominal CT showed a type 3 hydatid cyst involving the upper part of the left ventricle.
Image 3. CT scan section showing a type 3 multivesicular cyst located in the left ventricle

The patient was put on medical treatment (Albendazole®), and referred to surgery for management but the patient refused surgery so we left him on antiparasitic medical treatment.

3. DISCUSSION

Hydatid cysts of the heart are rare. The review of the literature has shown the predominance of the left ventricular location of hydatid cysts, i.e. 60%, which is explained by the importance of the muscular mass and the rich vascularization of the left ventricle [4-5]. The larvae arrive at the heart through the right cavities and pass into the systemic circulation by crossing the pulmonary filter and arrive at the myocardium through the coronary circulation. The interventricular septum is affected in 9 to 20% of cases, while the right ventricle and right atrium are affected in 4 to 17% and the interatrial septum in 2% [6]. In our case, fissuring of the ventricular cyst is the cause of the pericardial involvement. The symptomatology varies according to the number, location and integrity of the cysts. In some cases, a coronary picture is found, due to the passage of the larvae into the coronary circulation, giving a coronary syndrome due to compression of the coronary arteries [7]. The complications represented mainly by a pulmonary embolism, systemic, cerebral, ischemic syndrome or arrhythmia by compression of small coronary vessels and conduction tissue or a rupture in the pericardium as in the case of our patient. Echocardiography is a non-invasive and easily reproducible examination and remains the key examination for the diagnosis of cardiac hydatidosis. Cross-sectional imaging, in particular CT or MRI, allows a more precise topographical analysis and the study of the relationships with adjacent structures and an assessment of the extension of the cysts to all organs [8-9].

The curative treatment of cardiac hydatidosis is exclusively surgical [10]. It is systematic and must be done as early as possible in order to prevent the occurrence of complications, failing which medical treatment with ALBENDAZOLE can be used [11].

4. CONCLUSION

Despite its rarity, hydatitosis is not negligible in developing countries. It is serious and formidable because of its complications. The therapeutic management is delicate and often of partial effectiveness, hence the interest to privilege the preventive treatment.

CONSENT

As per international standard or university standard, patients’ written consent has been collected and preserved by the author(s).

ETHICAL APPROVAL
